

This report highlights the average nutrient status of corn across the state based on tissue samples submitted at the growth stage indicated. Nutrient levels are reported as deficient, responsive or adequate according to our NutriSolutions[®] sufficiency ranges.* The agronomic recommendations at the end of this report are based on the aggregated data sets from across the state and may not be representative of individual fields. Nutrient status is variable depending on a number of production and environmental factors, so consult with your agronomist for customized recommendations.

CORN Growth Stage: V4-8 Number of Samples Statewide: 796

Complete Nutrient Summary

● Deficient ● Responsive ● Adequate ● Excessive ● Deficient+Responsive

Bar graph indicates the percent of tissue samples that fall into each classification by nutrient. Line graph indicates the percent of tissue samples that are deficient or responsive by nutrient.

Nutrient Averages ppm

● Deficient ● Responsive ● Adequate ● Average Nutrient Value

Nutrient Averages (%)

● Deficient ● Responsive ● Adequate ● Average Nutrient Value

Each bar graph represents the NutriSolutions[®] sufficiency status by nutrient. The bar graph shows the average nutrient level based on tissue sampling results across the state.

Deficient/Responsive Nutrients (year over year)

● 2017 ● 2018 ● 2019 ● 2020 ● 2021

This graph compares the percent of tissue sample results that are deficient or responsive year over year.

AGRONOMIC ADVICE

The agronomic advice below is based on corn tissue samples analyzed from farms across the state of Iowa and may not be representative of every field. Work with your local agronomic advisor to develop custom recommendations based on tissue testing analysis of individual fields.

Early in development, boron is used in cell wall stability and structural integrity, as well as the movement of sugars/energy.

Manganese is required for photosynthesis, carbohydrate production and nitrogen utilization.

Early in corn development, zinc is important for conversion of starch to sugar. It is also used in cell elongation and division.

Potassium regulates carbon dioxide uptake in leaf tissue and is essential in plant energy production.

*Deficient means that the plant has not taken up enough of a specific nutrient to meet its physiological needs and will need a fertilizer application. A responsive result indicates that a crop is not yet deficient but could benefit from a foliar nutrient application. Nutrients that are in sufficient supply within the plant at the time of testing are reported as adequate.

Important: This report is being provided to you for information purposes only and for your private use in preparing your own agronomic plan. While every effort has been made to ensure the accuracy and reliability of the information, the information is gathered from across the specified state, and no guarantee is given or responsibility taken by WinField United relative to the accuracy or the applicability of the information to your particular circumstances or geography. Excessive nutrient levels — above the level for optimum growth and development — can cause issues with the uptake utilization of other nutrients. Please talk to your local agronomist about the issue. Soil and tissue sampling should be used together to help diagnose plant nutrient deficiencies. Soil sampling can give an indication of what nutrients are available in the soil, while tissue testing reveals the effectiveness of plant nutrient uptake.
